Data on Github

Download via the "Raw" button...

Can also use (e.g.) read_csv (in readr):

- > library(readr)

Generalized Least Squares Models

Start with a focus on residuals... For:

$$Y_{it} = \mathbf{X}_{it}\beta + u_{it}$$

i.i.d. OLS *uits* require:

$$\mathbf{u}\mathbf{u}' \equiv \mathbf{\Omega} = \sigma^2 \mathbf{I}$$

$$= \begin{pmatrix} \sigma^2 & 0 & \cdots & 0 \\ 0 & \sigma^2 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & \sigma^2 \end{pmatrix}$$

GLS Models

This means that within units:

- $Var(u_{it}) = Var(u_{is}) \ \forall \ t \neq s$ (temporal homoscedasticity)
- $Cov(u_{it}, u_{is}) = 0 \ \forall \ t \neq s$ (no within-unit autocorrelation)

and between units:

- $Var(u_{it}) = Var(u_{it}) \ \forall \ i \neq j$ (cross-unit homoscedasticity)
- Cov $(u_{it}, u_{jt}) = 0 \ \forall \ i \neq j$ (no between-unit / spatial correlation)

Estimator:

$$\hat{\beta}_{\textit{GLS}} = (\mathbf{X}' \mathbf{\Omega}^{-1} \mathbf{X})^{-1} \mathbf{X}' \mathbf{\Omega}^{-1} \mathbf{Y}$$

with:

$$\widehat{\mathsf{V}(\beta_{\mathit{GLS}})} = (\mathsf{X}'\Omega^{-1}\mathsf{X})^{-1}$$

Two approaches:

- ullet Use OLS \hat{u}_{it} s to get $\hat{\Omega}$ ("feasible GLS" / "weighted least squares")
- \bullet Use substantive knowledge about the data to structure Ω

Getting to Know WLS

The variance-covariance matrix is:

$$\begin{aligned} \mathsf{Var}(\hat{\beta}_{\mathit{WLS}}) &= & \sigma^2(\mathbf{X}'\Omega^{-1}\mathbf{X})^{-1} \\ &\equiv & (\mathbf{X}'\mathbf{W}^{-1}\mathbf{X})^{-1} \end{aligned}$$

A common case is:

$$\mathsf{Var}(u_i) = \sigma^2 \frac{1}{N_i}$$

where N_i is the number of observations upon which (aggregate) observation i is based.

"Robust" Variance Estimators

Recall that, if $\sigma_i^2 \neq \sigma_i^2 \forall i \neq j$,

$$Var(\beta_{Het.}) = (\mathbf{X}'\mathbf{X})^{-1}(\mathbf{X}'\mathbf{W}^{-1}\mathbf{X})(\mathbf{X}'\mathbf{X})^{-1}$$
$$= (\mathbf{X}'\mathbf{X})^{-1}\mathbf{Q}(\mathbf{X}'\mathbf{X})^{-1}$$

where $\mathbf{Q} = (\mathbf{X}'\mathbf{W}^{-1}\mathbf{X})$ and $\mathbf{W} = \sigma^2 \mathbf{\Omega}$.

We can rewrite **Q** as

$$\mathbf{Q} = \sigma^{2}(\mathbf{X}'\Omega^{-1}\mathbf{X})$$
$$= \sum_{i=1}^{N} \sigma_{i}^{2}\mathbf{X}_{i}\mathbf{X}'_{i}$$

Huber's Insight

Estimate **Q** as:

$$\widehat{\mathbf{Q}} = \sum_{i=1}^{N} \widehat{u}_i^2 \mathbf{X}_i \mathbf{X}_i'$$

Yields:

$$\widehat{\mathsf{Var}(\boldsymbol{\beta})}_{\mathsf{Robust}} = (\mathbf{X}'\mathbf{X})^{-1}(\mathbf{X}'\widehat{\mathbf{Q}}^{-1}\mathbf{X})(\mathbf{X}'\mathbf{X})^{-1} \\
= (\mathbf{X}'\mathbf{X})^{-1} \left[\mathbf{X}' \left(\sum_{i=1}^{N} \widehat{u}_{i}^{2}\mathbf{X}_{i}\mathbf{X}_{i}' \right)^{-1} \mathbf{X} \right] (\mathbf{X}'\mathbf{X})^{-1}$$

Practical Things

"Robust" VCV estimates:

- are heteroscedasticity-consistent, but
- are biased in small samples, and
- are less efficient than "naive" estimates when $Var(u) = \sigma^2 I$.

"Clustering"

Huber / White

????????

WLS / GLS

I know very little about my error variances... I know a great deal about my error variances...

"Clustering"

A common case:

$$Y_{ij} = \mathbf{X}_{ij}\boldsymbol{\beta} + u_{ij}$$

with

$$\sigma_{ij}^2 = \sigma_{ik}^2.$$

"Robust, clustered" estimator:

$$\widehat{\mathsf{Var}(\boldsymbol{\beta})}_{\mathsf{Clustered}} = (\mathbf{X}'\mathbf{X})^{-1} \left\{ \mathbf{X}' \left[\sum_{i=1}^{N} \left(\sum_{j=1}^{n_j} \hat{u}_{ij}^2 \mathbf{X}_{ij} \mathbf{X}_{ij}' \right) \right]^{-1} \mathbf{X} \right\} (\mathbf{X}'\mathbf{X})^{-1}$$

Serial Residual Correlation

Example:

$$Y_t = \beta_0 + \beta_1 X_t + u_t$$

$$u_t = \rho u_{t-1} + e_t$$

with $e_t \sim i.i.d. N(0, \sigma_u^2)$ and $\rho \in [-1, 1]$ (typically).

 \rightarrow "First-order autoregressive" ("AR(1)") errors.

Serially Correlated Errors and OLS

Detection

- Plot of residuals vs. lagged residuals
- Runs test (Geary test)
- Durbin-Watson d
 - · Calculated as:

$$d = \frac{\sum_{t=2}^{N} (\hat{u}_t - \hat{u}_{t-1})^2}{\sum_{t=1}^{N} \hat{u}_t^2}$$

- · Non-standard distribution $(d \in [0,4])$
- · Null: No autocorrelation
- · Only detects first-order autocorrelation

Serially Correlated Errors and OLS

What to do about it?

- GLS, incorporating $\rho / \hat{\rho}$ into the equation
- First-difference models (regressing changes of Y on changes of X)
- Cochrane-Orcutt / Prais-Winsten:
 - 1. Estimate the basic equation via OLS, and obtain residuals
 - 2. Use the residuals to consistently estimate $\hat{\rho}$ (i.e. the empirical correlation between u_t and u_{t-1})
 - 3. Use this estimate of $\hat{\rho}$ to estimate the difference equation:

$$(Y_t - \rho Y_{t-1}) = \beta_0(1 - \rho) + \beta_1(X_t - \rho X_{t-1}) + (u_t - \rho u_{t-1})$$

- 4. Save the residuals, and use them to estimate $\hat{\rho}$ again
- 5. Repeat this process until successive estimates of $\hat{\rho}$ differ by a very small amount

Running Example Redux

The World Development Indicators:

- Cross-national country-level time series data
- N = 215 countries, T = 73 years (1960-2022) + missingness
- Full descriptions are listed in the Github repo here

Regression model:

$$\begin{split} \mathsf{WBLI}_{it} &= \beta_0 + \beta_1 \mathsf{Population} \; \mathsf{Growth}_{it} + \beta_2 \mathsf{Urban} \; \mathsf{Population}_{it}^2 + \beta_3 \mathsf{Fertility} \; \mathsf{Rate}_{it} + \\ & \beta_4 \mathsf{In} \big(\mathsf{GDP} \; \mathsf{Per} \; \mathsf{Capita}\big)_{it} + \beta_5 \mathsf{Natural} \; \mathsf{Resource} \; \mathsf{Rents}_{it} + \beta_6 \mathsf{Cold} \; \mathsf{War}_t + u_{it} \end{split}$$

How Much Autocorrelation in X?

Note that:

$$d = 2(1 - \rho)$$

which means that we can calculate:

$$\rho=1-\frac{d}{2}.$$

Autocorrelation in the Predictors

	Variable	Rho
1	Population Growth	0.852

Some Panel Data Challenges

Consider the error terms in the model:

$$Y_{it} = \mathbf{X}_{it}\boldsymbol{\beta} + u_{it}$$

Issues:

<u>In Words</u> :	<u>In a Formula</u> :
<u>Variances</u> :	
Unit-Wise Heteroscedasticity	$Var(u_{it}) \neq Var(u_{jt})$
Temporal Heteroscedasticity	$Var(u_{it}) \neq Var(u_{is})$
<u>Covariances</u> :	
Contemporary Cross-Unit Correlation	$Cov(u_{it}, u_{jt}) \neq 0$
Within-Unit Serial Correlation	$Cov(u_{it}, u_{is}) \neq 0$
Non-Contemporaraneous Cross-Unit Correlation	$Cov(u_{it},u_{js}) \neq 0$

Parks' (1967) Approach

Assume:

- $Var(u_{it}, u_{jt}) = \sigma^2$ or σ_i^2 (Common or unit-specific error variances)
- $Var(u_{it}) = Var(u_{is}) \ \forall \ t \neq s$ (Temporal homoscedasticity)
- $Cov(u_{it}, u_{it}) = \sigma_{ii} \ \forall \ i \neq j$ (Pairwise contemporaneous cross-unit correlation)
- Cov $(u_{it}, u_{is}) = \rho$ or ρ_i (Common or unit-specific temporal correlation)
- Cov $(u_{it}, u_{js}) = 0 \ \forall \ i \neq j, t \neq s$ (No non-contemporaneous cross-unit correlation)

(B&K: "panel error assumptions").

Then:

- 1. Use OLS to generate \hat{u} s $ightarrow \hat{
 ho}$ ($ightarrow \hat{m{\Omega}}$),
- 2. Use $\hat{\rho}$ for Prais-Winsten.

This method was widely used prior to Beck & Katz (1995)

Parks' Problems

$$\boldsymbol{\Omega} = \begin{pmatrix} \boldsymbol{\Sigma} & \boldsymbol{0} & \cdots & \boldsymbol{0} \\ \boldsymbol{0} & \boldsymbol{\Sigma} & \cdots & \boldsymbol{0} \\ \vdots & \vdots & \ddots & \vdots \\ \boldsymbol{0} & \boldsymbol{0} & \cdots & \boldsymbol{\Sigma} \end{pmatrix} = \boldsymbol{\Sigma} \otimes \boldsymbol{I}_{\mathcal{T}}$$

where

$$\sum_{N\times N} = \begin{pmatrix} \sigma_1^2 & \sigma_{12} & \cdots & \sigma_{1N} \\ \sigma_{12} & \sigma_2^2 & \cdots & \sigma_{2N} \\ \vdots & \vdots & \ddots & \vdots \\ \sigma_{1N} & \sigma_{2N} & \cdots & \sigma_N^2 \end{pmatrix}$$

Means:

- $\frac{N(N-1)}{2}$ distinct contemporaneous covariances σ_{ij} ,
- NT observations,
- ightarrow 2T/(N+1) observations per $\hat{\sigma}$

More Parks Problems

From PROC PANEL in SAS:

Standard Corrections

For the PARKS option, the first-order autocorrelation coefficient must be estimated for each cross section. Let ρ be the $N \times 1$ vector of true parameters and $R = (r_1, \dots, r_N)'$ be the corresponding vector of estimates. Then, to ensure that only range-preserving estimates are used in PROC PANEL, the following modification for R is made:

$$r_i = \begin{cases} r_i & \text{if } |r_i| < 1\\ \max(.95, \text{rmax}) & \text{if } r_i \ge 1\\ \min(-.95, \text{rmin}) & \text{if } r_i \le -1 \end{cases}$$

where

$$\operatorname{rmax} = \begin{cases} 0 & \text{if} \quad r_i < 0 \quad \text{or} \quad r_i \ge 1 \quad \forall i \\ \max_j [r_j : 0 \le r_j < 1] & \text{otherwise} \end{cases}$$

and

$$\mathrm{rmin} = \begin{cases} 0 & \text{if} \quad r_i > 0 \quad \text{or} \quad r_i \leq -1 \quad \forall i \\ \max_j [r_j: -1 < r_j \leq 0] & \text{otherwise} \end{cases}$$

Whenever this correction is made, a warning message is printed.

Panel-Corrected Standard Errors

Key to PCSEs:

$$\hat{\sigma}_{ij} = \frac{\sum_{t=1}^{T} \hat{u}_{it} \hat{u}_{jt}}{T}$$

Define:

$$\mathbf{U}_{T \times N} = \begin{pmatrix} \hat{u}_{11} & \hat{u}_{21} & \cdots & \hat{u}_{N1} \\ \hat{u}_{12} & \hat{u}_{22} & \cdots & \hat{u}_{N2} \\ \vdots & \vdots & \ddots & \vdots \\ \hat{u}_{1T} & \hat{u}_{2T} & \cdots & \hat{u}_{NT} \end{pmatrix}$$

$$\hat{\mathbf{\Sigma}} = \frac{(\mathbf{U}'\mathbf{U})}{T}$$

$$\hat{\Omega}_{\textit{PCSE}} = \frac{(\textbf{U}'\textbf{U})}{\textit{T}} \otimes \textbf{I}_{\textit{T}}$$

Panel-Corrected Standard Errors

Correct formula:

$$\mathsf{Cov}(\hat{eta}_{PCSE}) = (\mathbf{X}'\mathbf{X})^{-1}[\mathbf{X}'\mathbf{\Omega}\mathbf{X}](\mathbf{X}'\mathbf{X})^{-1}$$

General Issues:

- PCSEs do not fix unit-level heterogeneity (a la "fixed" / "random" effects)
- They also do not deal with dynamics
- They depend critically on the "panel data assumptions" of Park / Beck & Katz

Panel Assumptions and Numbers of Parameters

Panel Assumptions	No AR(1)	Common $\hat{ ho}$	Separate $\hat{ ho}_i$ s
$\sigma_i^2 = \sigma^2$, $Cov(\sigma_{it}, \sigma_{jt}) = 0$	k+1	k + 2	k + N + 1
$\sigma_i^2 \neq \sigma^2$, $Cov(\sigma_{it}, \sigma_{jt}) = 0$	k + N	k + N + 1	k + 2N
$\sigma_i^2 \neq \sigma^2$, $Cov(\sigma_{it}, \sigma_{jt}) \neq 0$	$\frac{N(N-1)}{2} + k + N$	$\frac{N(N-1)}{2} + k + N + 1$	$\frac{N(N-1)}{2} + k + 2N$

Example: GLS with Homoscedastic AR(1) Errors

```
> GLS<-gls(WomenBusLawIndex~PopGrowth+UrbanPopulation+FertilityRate+log(GDPPerCapita)+NaturalResourceRents+ColdWar,

Model Comparisons

Dynamics!

Time Series: Stationarity

Stationarity: A constant d.g.p. over time.¹

Mean stationarity:

$$E(Y_t) = \mu \ \forall \ t$$

Variance stationarity:

$$Var(Y_t) = E[(Y_t - \mu)^2] \equiv \sigma_Y^2 \ \forall \ t$$

Covariance stationarity:

$$Cov(Y_t, Y_{t-s}) = E[(Y_t - \mu)(Y_{t-s} - \mu)] = \gamma_s \ \forall \ s$$

 $^{^1\}text{A}$ stricter form of stationarity requires that the joint probability distribution (in other words, all the moments) of series of observations $\{Y_1,Y_2,...Y_t\}$ is the same as that for $\{Y_{1+s},Y_{2+s},...Y_{t+s}\}$ for all t and s.

The "ARIMA" Approach

"ARIMA" = Autoregressive Integrated Moving Average...

A (first-order) integrated series ("random walk") is:

$$Y_t = Y_{t-1} + u_t, \ u_t \sim i.i.d.(0, \sigma_u^2)$$

...a/k/a a "random walk":

$$Y_{t} = Y_{t-2} + u_{t-1} + u_{t}$$

$$= Y_{t-3} + u_{t-2} + u_{t-1} + u_{t}$$

$$= \sum_{t=0}^{T} u_{t}$$

I(1) Series Properties

I(1) series are not stationary.

Variance:

$$Var(Y_t) \equiv E(Y_t)^2 = t\sigma^2$$

Autocovariance:

$$Cov(Y_t, Y_{t-s}) = |t - s|\sigma^2.$$

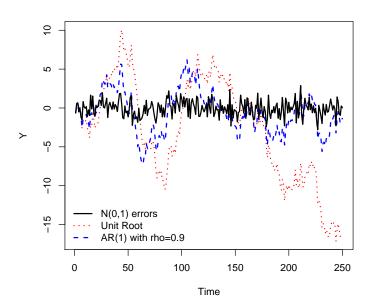

Both depend on t...

I(1) series (continued)

More generally:

- $|\rho| > 1$
 - Series is nonstationary / explosive
 - Past shocks have a greater impact than current ones
 - Uncommon
- $|\rho| < 1$
 - Stationary series
 - ullet Effects of shocks die out exponentially according to ho
 - Is mean-reverting
- \bullet $|\rho|=1$
 - Nonstationary series
 - Shocks persist at full force
 - Not mean-reverting; variance increases with t

Time Series Types, Illustrated

I(1) Series: Differencing

For an I(1) series:

$$Y_t - Y_{t-1} = u_t$$

which we often write in terms of the difference operator Δ (or sometimes ∇):

$$\Delta Y_t = u_t$$

The differenced series is just the (stationary, ergoditic) white-noise process u_t .

Unit Root Tests Review: Dickey-Fuller

Two steps:

- Estimate $Y_t = \rho Y_{t-1} + u_t$,
- test the hypothesis that $\hat{\rho} = 1$, but
- this requires that the *u*s are uncorrelated.

But suppose:

$$\Delta Y_t = \sum_{i=1}^p d_i \Delta Y_{t-i} + u_t$$

which yields

$$Y_t = Y_{t-1} + \sum_{i=1}^{p} d_i \Delta Y_{t-i} + u_t.$$

D.F. tests will be incorrect.

Unit Root Alternatives

Augmented Dickey-Fuller Tests:

Estimate

$$\Delta Y_t = \rho Y_{t-1} + \sum_{i=1}^p d_i \Delta Y_{t-i} + u_t$$

• Test $\hat{
ho}=0$ (vs. alternative that $\hat{
ho}<0$)

Phillips-Perron Tests:

• Estimate:

$$\Delta Y_t = \alpha + \rho Y_{t-1} + u_t$$

- Calculate modified test statistics (Z_{ρ} and Z_{t})
- Test $\hat{\rho} = 0$

Issues with Unit Roots in Panel Data

- Short series + Asymptotic tests → "borrow strength"
- Requires uniform unit roots across cross-sectional units
- Many tests require balanced panels...
- Various alternatives:
 - Maddala and Wu (1999)
 - Hadri (2000)
 - Levin, Lin and Chu (2002)
 - Im, Pesaran, and Shin (2003)
- What to do?
 - Difference the data...
 - Error-correction models

Panel Unit Root Tests: R

```
[data wrangling...]
> purtest(WBLI.W,exo="trend",test="levinlin",pmax=2)
Levin-Lin-Chu Unit-Root Test (ex. var.: Individual Intercepts and Trend)
data: WBLT.W
z = -2.7, p-value = 0.004
alternative hypothesis: stationarity
> purtest(WBLI.W,exo="trend",test="hadri",pmax=2)
Hadri Test (ex. var.: Individual Intercepts and Trend) (Heterosked. Consistent)
data: WBLI.W
z = 197, p-value <2e-16
alternative hypothesis: at least one series has a unit root
> purtest(WBLI.W,exo="trend",test="madwu",pmax=2)
Maddala-Wu Unit-Root Test (ex. var.: Individual Intercepts and Trend)
data: WBLI.W
chisq = 364, df = 376, p-value = 0.7
alternative hypothesis: stationarity
> purtest(WBLI.W,exo="trend",test="ips",pmax=2)
Im-Pesaran-Shin Unit-Root Test (ex. var.: Individual Intercepts and Trend)
data: WBLT.W
Wtbar = 2.8, p-value = 1
alternative hypothesis: stationarity
```

A Better Table

	Test	Alternative	Statistic	Estimate	P-Value
1	Levin-Lin-Chu Unit-Root Test	stationarity	z	-2.672	0.0038
2	Hadri Test	at least one series has a unit root	Z	196.75	< 0.0001
3	Maddala-Wu Unit-Root Test	stationarity	χ^2	363.89	0.6635
4	Im-Pesaran-Shin Unit-Root Test	stationarity	\bar{W}_t	2.77	0.9972

Note: All assume individual intercepts and trends.

Lagged Y?

"Lagged dependent variable":

$$Y_{it} = \phi Y_{it-1} + \mathbf{X}_{it} \boldsymbol{\beta}_{LDV} + \epsilon_{it}$$

If ϵ_{it} is perfect, then:

- $\hat{\beta}_{LDV}$ is biased (but consistent),
- O(bias) = $\frac{-1+3\beta_{LDV}}{T}$

If ϵ_{it} is autocorrelated...

- $\hat{\beta}_{LDV}$ is biased and inconsistent
- IV is one (bad) option...

Lagged Ys and GLS-ARMA

Can rewrite:

$$Y_{it} = \mathbf{X}_{it} \boldsymbol{\beta}_{AR} + u_{it}$$

 $u_{it} = \phi u_{it-1} + \eta_{it}$

as

$$Y_{it} = \mathbf{X}_{it}\beta_{AR} + \phi u_{it-1} + \eta_{it}$$

$$= \mathbf{X}_{it}\beta_{AR} + \phi(\mathbf{Y}_{it-1} - \mathbf{X}_{it-1}\beta_{AR}) + \eta_{it}$$

$$= \phi \mathbf{Y}_{it-1} + \mathbf{X}_{it}\beta_{AR} + \mathbf{X}_{it-1}\psi + \eta_{it}$$

where $\psi = \phi \beta_{AR}$ and $\psi = 0$ (by assumption).

Lagged Ys and World Domination

In:

$$Y_{it} = \phi Y_{it-1} + \mathbf{X}_{it} \boldsymbol{\beta}_{LDV} + \epsilon_{it}$$

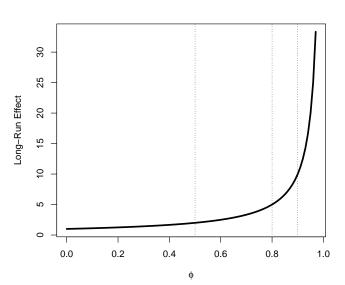

Achen: Bias "deflates" $\hat{\beta}_{LDV}$ relative to $\hat{\phi}$, "suppress" the effects of **X**...

Keele & Kelly (2006):

- Contingent on ϵ s having autocorrelation
- Key: In LDV, long-run impact of a unit change in X is:

$$\hat{eta}_{LR} = rac{\hat{eta}_{LDV}}{1 - \hat{\phi}}$$

Long-Run Impact for $\hat{eta}=1$

Lagged Ys and Unit Effects

Consider:

$$Y_{it} = \phi Y_{it-1} + \mathbf{X}_{it} \boldsymbol{\beta} + \alpha_i + u_{it}.$$

If we omit the unit effects, we have:

$$Y_{it} = \phi Y_{it-1} + \mathbf{X}_{it} \boldsymbol{\beta} + u_{it}^*$$

with

$$u_{it}^* = \alpha_i + u_{it}$$

Lagging yields:

$$Y_{it-1} = \phi Y_{it-2} + \mathbf{X}_{it-1} \boldsymbol{\beta} + \alpha_i + u_{it-1}$$

which means

$$Cov(Y_{it-1}, u_{it}^*) \neq 0. \rightarrow bias in \hat{\phi}, \hat{\beta}$$

"Nickell" Bias

Bias in $\hat{\phi}$ is

- toward zero when $\phi > 0$,
- increasing in ϕ .

Including unit effects still yields bias in $\hat{\phi}$ of $O(\frac{1}{T})$, and bias in $\hat{\beta}$.

Solutions:

- Difference/GMM estimation
- Bias correction approaches

First Difference Estimation

$$Y_{it} - Y_{it-1} = \phi(Y_{it-1} - Y_{it-2}) + (\mathbf{X}_{it} - \mathbf{X}_{it-1})\beta + (\alpha_i - \alpha_i) + (u_{it} - u_{it-1})$$

$$\Delta Y_{it} = \phi\Delta Y_{it-1} + \Delta \mathbf{X}_{it}\beta + \Delta u_{it}$$

Anderson/Hsiao: If \nexists autocorrelation, then use ΔY_{it-2} or Y_{it-2} as instruments for ΔY_{it-1} ...

- Consistent in theory,
- in practice, the former is preferred, and both have issues if ϕ is high;
- both are inefficient.

$A&H \rightarrow A&B$

Arellano & Bond (also Wawro): Use *all* lags of Y_{it} and \mathbf{X}_{it} from t-2 and before.

- "Good" estimates, better as $T \to \infty$,
- Easy to handle higher-order lags of Y,
- Easy software (plm in R , xtabond in Stata).
- Model is fixed effects...
- \mathbf{Z}_i has T-p-1 rows, $\sum_{i=p}^{T-2} i$ columns \rightarrow difficulty of estimation declines in p, grows in T.

Bias-Correction Models

Kiviet (1995, 1999; Bun and Kiviet 2003; Bruno 2005a,b): Derive the bias in $\hat{\phi}$ and $\hat{\beta}$, then correct it...

- \bullet More accurate than the instrumental-variables/GMM estimators of A&H/A&B...
- ...especially when T is small; but not as T gets reasonably large ($T \approx 20$)

p < 0.05

Anderson-Hsiao, Arellano-Bond, etc.

In R:

- Anderson-Hsiao can be fit using Im or (more easily) plm in the plm package
- Arellano-Bond is most easily fit using pgmm ("panel gmm") in the plm package
- See Criossant and Millo (2018, Chapter 7) for statistics + code details
- This post is also useful...

Stata:

- xtabond / xtdpdsys / xtdpd fit both A-H and A-B / Blundell-Bond models (among others)
- This is also a good (slightly dated) reference

Trends!

What if *Y* is *trending* over time?

- First Question: Why?
 - · Organic growth (e.g., populations)
 - · Temporary / short-term factors
 - · Covariates...
- Second question: Should we care? (A: Yes, usually... \rightarrow "spurious regressions")
- Third question: What to do?
 - · Ignore it...
 - Include a counter / trend term...

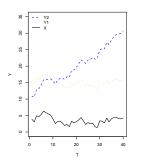

In general, adding a trend term will decrease the magnitudes of $\hat{\beta}$...

Trends Matter, Illustrated

Data generating processes:

$$Y_{1t} = 10 + (1 \times X_t) + u_t$$

$$Y_{2t} = 5 + (1 \times X_t) + (0.5 \times T) + u_t$$

Another Approach: Orthogonalization

Note: We're rarely substantively interested in the fixed effects $\hat{\alpha}$...

- \rightarrow reparameterize the α s so that they are *information-orthogonal* to the other parameters in the model (including the β s and ϕ)
- Key idea: Transform the α s so that (for example):

$$\mathsf{E}\left(\frac{\partial^2 L_i}{\partial \alpha \partial \beta}\right) = 0$$

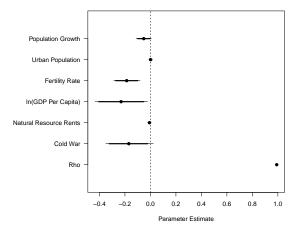

- Can do this via imposition of priors, in a Bayesian framework...
- In general, this approach is less assumption-laden and more efficient than the IV/GMM-based approaches discussed above.
- Provides consistent-in-N estimates for T as low as 2...

Fertility Rate	-0.1864	-20.1788
In(GDP Per Capita)	-0.2303	-25.5141
Natural Resource Rents	-0.0075	-0.8048
Cold War	-0.1697	-18.3407

Dynamic Models: Software

R:

- the plm package (purtest for unit roots; plm for first-difference models; pgmm for Arellano-Bond)
- the panelAR package (GLS-ARMA models)
- the gls package (GLS)
- the dynpanel package (A&H, A&B; minimal...)

Stata:

- xtgls (GLS)
- xtpcse (PCSEs)
- xtabond / xtdpd (A&H A&B dynamic models)

Final Thoughts: Dynamic Panel Models

Things to consider:

- N vs. T...
- Are dynamics nuisance or substance?
- What problem(s) do you really care about?
